

APPENDIX A. COMPUTATIONS

T. COATES (IMPERIAL COLLEGE LONDON), E. KALASHNIKOV (IMPERIAL COLLEGE LONDON), A.
KASPRZYK (UNIVERSITY OF NOTTINGHAM)

In this appendix, we describe the computer search for four dimensional Fano quiver flag zero loci with codimension at most four. Code to perform this and similar analyses, using the computational algebra system Magma [3], is available at the repository [1]. A database of Fano quiver flag varieties, which was produced as part of the calculation, is available at the repository [2].

A.1. Classifying quiver flag varieties. The first step is to find all Fano quiver flag varieties of dimension at most 8. A non-negative integer matrix $A = [a_{i,j}]_{0 \leq i,j \leq \rho}$ and a dimension vector $\mathbf{r} \in \mathbb{Z}_{>0}^{\rho+1}$ determine a vertex-labelled directed multi-graph: the $\rho+1$ vertices are labelled by the r_i , and the adjacency matrix for the graph is A . Such a graph, if it is acyclic with a unique source, and the label of the source is 1, also determines a quiver flag variety. Two (A, \mathbf{r}) pairs can determine the same graph and hence the same quiver flag varieties.

Definition A.1. *A pair (A, \mathbf{r}) determining a quiver flag variety is in normal form if \mathbf{r} is increasing and, under all permutations of the $\rho+1$ indices that preserve \mathbf{r} , the columns of A are lex minimal.*

Two pairs in normal form determine the same quiver flag variety (and hence the same graph) if and only if they are equal.

Recall that quiver flag varieties are towers of Grassmannians, and that the i th step in the tower is given by the relative Grassmannian $\mathrm{Gr}(\mathcal{F}_i, r_i)$, where \mathcal{F}_i is a vector bundle of rank s_i . Using this construction it is easy to see that if $s_i = r_i$ then this quiver flag variety is equivalent to the quiver flag variety \tilde{Q} with vertex i removed, and one arrow $k \rightarrow j$ for every path of the form $k \rightarrow i \rightarrow j$. Therefore we can assume that $s_i > r_i$, and hence that every vertex contributes strictly positively to the dimension of the quiver flag variety. With this constraint, there are only finitely many quiver flag varieties with dimension at most 8, and each such has at most 9 vertices.

The algorithm to build all quiver flag varieties with dimension at most 8 is as follows. Start with the set S of all Grassmannians of dimension at most 8. Given an element of S of dimension less than 8, add one extra labelled vertex and extra arrows into this vertex, in all possible ways such that the dimension of the resulting quiver flag variety is at most 8. Put these in normal form and include them in S . Repeat until there are no remaining elements of S of dimension less than 8.

In this way we obtain all quiver flag varieties of dimension at most 8. We then compute the ample cone and anti-canonical bundle for each, and discard any which are not Fano. We find 223044 Fano quiver flag varieties of dimension at most 8; 223017 of dimension $4 \leq d \leq 8$. Of these 50617 (respectively 50612) are non-toric quiver flag varieties.

TABLE 1. The number of Fano quiver flag varieties by dimension d and Picard rank ρ

Remark A.2. *In our codebase we define new Magma intrinsics `QuiverFlagVariety(A, r)`, which creates a quiver flag variety from an adjacency matrix A and dimension vector \mathbf{r} , and*

`QuiverFlagVarietyFano(id),`

which creates a Fano quiver flag variety, in normal form, from its ID [1, 2]. We assign IDs to Fano quiver flag varieties of dimension at most 8, in the range {1 … 223044}, by placing them in normal form and then ordering them first by dimension, then by Picard rank, then lexicographically by dimension vector, then lexicographically by the columns of the adjacency matrix. We also define *Magma intrinsics NefCone(Q)*, *MoriCone(Q)*, *PicardLattice(Q)*, and *CanonicalClass(Q)* that compute the nef cone, Mori cone, Picard lattice and canonical class of a quiver flag variety Q , and an intrinsic *PeriodSequence(Q, 1)* that computes the first $l + 1$ terms of the Taylor expansion of the regularised quantum period of Q . See §A.5 for more details.

A.2. The class of vector bundles that we consider. We consider all bundles E on a given quiver flag variety that:

- are direct sums of bundles of the form

$$(1) \quad L \otimes S^{\alpha_1}(W_1) \otimes \cdots \otimes S^{\alpha_\rho}(W_\rho)$$

where each S^{α_i} is a non-negative Schur power and L is a nef line bundle; and

- have rank c , where c is four less than the dimension of the ambient quiver flag variety.

Remark 3.2 shows that non-negative Schur powers $S^\alpha(W_i)$ are globally generated, and Proposition 5.15 shows that nef line bundles are globally generated. Since the tensor product of globally generated vector bundles is globally generated, the first condition ensures that E is globally generated. In particular, therefore, the zero locus X of a generic section of E is smooth. The second condition ensures that the zero locus X , if non-empty, is a fourfold. Global generation also implies that the bundle E is convex, which allows us to compute the quantum period of X as described in §6.1.

Consider a summand as in (1). We can represent the partition α_i as a length r_i decreasing sequence of non-negative integers, and write $L = \bigotimes_{j=1}^{\rho} (\det W_j)^{a_j}$ where a_j may be negative. Therefore each such summand is determined by a length ρ sequence of *generalised partitions*: the partition (with possibly negative entries) corresponding to index i is $\alpha_i + (a_i, \dots, a_i)$.

Remark A.3. In our codebase we define a new *Magma intrinsic*

`QuiverFlagBundle(Q, [A1, ..., Ak])`

which creates a bundle of the above form, on the quiver flag variety Q , from a sequence of generalised partitions (A_1, \dots, A_k) . We also define an intrinsic *FirstChernClass(E)* that computes the first Chern class of such a bundle E ; *intrinsics Degree(E)* and *EulerNumber(E)* that compute the degree and Euler number¹ of the zero locus X of a generic section of E ; and *intrinsics HilbertCoefficients(E, 1)* and *PeriodSequence(E, 1)* that compute the first $l + 1$ terms of, respectively, the Hilbert series of X and the Taylor expansion of the regularised quantum period of X . See §A.5.

A.3. Classifying quiver flag bundles. In this step, we describe the algorithm for determining all bundles on a given quiver flag variety that determine a smooth four-dimensional Fano quiver flag zero locus. A vector bundle as above is determined by a tuple (A, \mathbf{r}, P) , where A is an adjacency matrix, \mathbf{r} is a dimension vector, and $P = (P_1, \dots, P_k)$ is a sequence where each P_i is a length- ρ sequence of generalised partitions such that the j th partition in each P_i is of length r_j . Note that we regard the summands (1) in our vector bundles as unordered; also, as discussed above, different pairs (A, \mathbf{r}) can determine the same quiver flag variety. We therefore say that a tuple (A, \mathbf{r}, P) is in *normal form* if the pair (A, \mathbf{r}) is in normal form, P is in lex order, and under all permutations of the vertices preserving these conditions, the sequence P is lex minimal; we work throughout with tuples in normal form.

Given a Fano quiver flag variety $M(Q, \mathbf{r})$ of dimension $4 + c$, $c \leq 4$, with anti-canonical class $-K_Q$ and nef cone $\text{Nef}(Q)$, we search for all bundles E such that

- E is a direct sum of bundles of the form (1);
- $\text{rank}(E) = c$;
- $-K_Q - c_1(E) \in \text{Amp}(Q)$.

The last condition ensures that the associated quiver flag zero locus X , if non-empty, is Fano. We proceed as follows. We first find all possible summands that can occur; that is, all irreducible vector bundles E of the form (1) such that $\text{rank}(E) \leq c$ and $-K_Q - c_1(E) \in \text{Amp}(Q)$. Let $\text{Irr}(Q)$ be the

¹This is the Euler characteristic of X as a topological space.

set of all such bundles. Write $\text{Irr}(Q) = \text{Irr}(Q)_1 \sqcup \text{Irr}(Q)_2$, where $\text{Irr}(Q)_1$ contains vector bundles of rank strictly larger than 1, and $\text{Irr}(Q)_2$ contains only line bundles. We then search for two vector bundles E_1, E_2 such that E_i is a direct sum of bundles from $\text{Irr}(Q)_i$ and that $E = E_1 \oplus E_2$ satisfies the conditions above.

For each $x \in \text{Nef}(Q)$ such that $-K_Q - x$ is ample, we find all possible ways to write x as

$$(2) \quad x = \sum_{i=1}^l a_i$$

where the a_i are (possibly repeated) elements of a Hilbert basis for $\text{Nef}(Q)$. There are only finitely many decompositions (2); finding them efficiently is a knapsack-type problem that has already been solved [6]. For each $\tilde{c} \leq c$ and each partition of the a_i into at most $c/2$ groups S_1, \dots, S_s , we find all possible choices of $F_1, \dots, F_s \in \text{Irr}_1$ such that

$$c_1(F_i) = \sum_{j \in S_i} a_j \quad \text{rank}(F_1) + \dots + \text{rank}(F_s) = \tilde{c}.$$

Set $E_1 = F_1 \oplus \dots \oplus F_s$. Then for each $y \in \text{Nef}(Q)$ such that $-K_Q - x - y$ is ample, we again find all ways of writing

$$y = \sum_{j=1}^m b_j$$

as a sum of Hilbert basis elements. Each partition of the b_j into $c - \tilde{c}$ groups gives a choice of nef line bundles $L_1, \dots, L_{c-\tilde{c}} \in \text{Irr}_2(Q)$, and we set $E_2 = \oplus L_j$.

Remark A.4. *Treating the higher rank summands Irr_2 and line bundles Irr_1 separately here is not logically necessary, but it makes a huge practical difference to the speed of the search.*

A.4. Classifying quiver flag zero loci. For each of the Fano quiver flag varieties Q of dimension between 4 and 8, found in §A.1, we use the algorithm described in §A.3 to find all bundles on Q of the form described in §A.2. This produces 10788446 bundles. Each such bundle E determines a quiver flag zero locus X that is either empty or a smooth Fano fourfold. We discard any varieties that are empty or disconnected, and for the remainder compute the first fifteen terms of the Taylor expansion of the regularised quantum period of X , using Theorem 6.4. For many of the quiver flag zero loci that we find, this computation is extremely expensive (the main factor is the Picard rank of the abelianised quiver, as this determines the size of the cohomology ring of the abelianised quiver flag variety where the computations are done; Gröbner basis calculations that allow the computation of products in this ring become more expensive as the size of the ring grows). In practice, therefore, it is essential to use the equivalences described in §4 to replace such quiver flag zero loci by equivalent and more tractable models. The number of equivalence classes is far smaller than the number of quiver flag zero loci that we found, and so this replaces roughly 10 million calculations, many of which are hard, by around half a million calculations, almost all of which are easy. In this way we find 749 period sequences. We record these period sequences, together with the construction, Euler number, and degree for a representative quiver flag zero locus, in Appendix B below. 141 of the period sequences that we find are new. Thus we find at least 141 new four-dimensional Fano manifolds².

Remark A.5. *A computationally cheap sufficient condition for a quiver flag zero locus to be empty arises as follows. If W is the tautological quotient bundle on $\text{Gr}(n, r)$, where $2r - 1 > n$, then a generic global section of $\wedge^2 W$ or $\text{Sym}^2 W$ has an empty zero locus. Thus if i is a vertex in a quiver Q such that all arrows into i are from the source, and $2r_i - 1 > n_{0i} = s_i$, then there are no global sections of $\wedge^2 W_i$ or $\text{Sym}^2 W_i$ with non-empty zero locus: to see this, apply Proposition 3.1 to Q .*

²To be precise: we find at least 141 four-dimensional Fano manifolds for which the regularised quantum period was not previously known. The regularised quantum period of a Fano manifold X is expected to completely determine X . See [5, 6] for known quantum periods.

A.5. Cohomological computations for quiver flag zero loci. In this section we describe how we compute the degree, Euler characteristic, Hilbert series, and Taylor expansion of the regularised quantum period for quiver flag varieties and quiver flag zero loci. This relies on Martin’s integration formula [7] and Theorem 6.1.

Let V be a smooth projective variety with an action of G on V , let T be a maximal torus in G , and consider the GIT quotients $V//G$ and $V//T$ determined by a character of G . Let $\pi : V^{ss}(G)/T \rightarrow V//G$ be the projection and $i : V^{ss}(G)/T \rightarrow V^{ss}(T)/T = V//T$ be the inclusion. Let W be the Weyl group, and $e = \prod_{\lambda \in Roots(G)} c_1(L_\lambda)$, where L_λ is the line bundle on $V//T$ associated to the character λ .

Theorem A.6 (Martin’s Integration Formula, [7]). *For any $a \in H^*(V//G, \mathbb{C})$ and any $\tilde{a} \in H^*(V//T, \mathbb{C})$ satisfying $\pi^*(a) = i^*(\tilde{a})$*

$$\int_{V//G} a = \frac{1}{|W|} \int_{V//T} \tilde{a} \cup e.$$

If $a \in H^*(V//G, \mathbb{C})$ and $\tilde{a} \in H^*(V//T, \mathbb{C})$ satisfy $\pi^*(a) = i^*(\tilde{a})$ then we say that \tilde{a} is a lift of a .

In our case the Abelianization $V//T$ is a smooth toric variety, and the cohomology rings of such varieties, being Stanley–Reisner rings, are easy to work with computationally [3, 13]. For example, we can use this to compute the number of components $h^0(X, \mathcal{O}_X)$ of a Fano quiver flag zero locus X . By Kodaira vanishing, $h^0(X, \mathcal{O}_X) = \chi(X)$, and applying the Hirzebruch–Riemann–Roch theorem gives

$$(3) \quad \chi(\mathcal{O}_X) = \int_X ch(\mathcal{O}_X) \cup Td(T_X) = \int_X Td(T_X).$$

We need to find a lift of the Todd class of T_X . Writing T_X as a K-theoretic quotient of representation theoretic bundles via the Euler sequence, as in the proof of Theorem 6.1, gives the lift that we seek; we then use Martin’s formula to reduce the integral (3) to an integral in the cohomology ring of the Abelianization. The same approach allows us to compute the first two terms $\chi(X, -K_X)$, $\chi(X, -2K_X)$ of the Hilbert series of X – which determine the entire Hilbert series, since X is a Fano fourfold – as well as the degree and Euler characteristic of X . To compute the first few Taylor coefficients of the quantum period of X , we combine this approach with the explicit formula in Theorem 6.1.

APPENDIX B. REGULARIZED QUANTUM PERIODS FOR QUIVER FLAG ZERO LOCI

T. COATES, E. KALASHNIKOV, A. KASPRZYK

B.1. The table of representatives. As described in Appendix A, we divided the 4-dimensional quiver flag zero loci X that we found into 749 buckets, according to the first 15 terms of the Taylor expansion of the regularised quantum period of X . We refer to these Taylor coefficients as the period sequence. Table 1 below gives, for each of the 749 period sequence buckets, a representative quiver flag zero locus X as well as the degree and Euler number of X . (In some cases we do not know that all the quiver flag zero loci in a bucket are isomorphic, but we checked that they all have the same degree, Euler number, and Hilbert series.) The quiver flag zero locus X is represented by the adjacency matrix and dimension vector of its ambient quiver flag variety $Y = M(Q, \mathbf{r})$, together with the sequence of generalised partitions that determine a vector bundle $E \rightarrow Y$ such that X is the zero locus of a generic section of E . The generalised partitions are written as Young diagrams, with:

- \emptyset representing the empty Young diagram;
- a filled Young diagram, such as $\blacksquare\blacksquare$, representing the dual to the vector bundle represented by the unfilled Young diagram $\square\square$.

Filled Young diagrams that occur always represent line bundles.

The entries in Table 1 give representatives of each period sequence bucket that are chosen so as to make the computation of geometric data (the period sequence etc.) straightforward³. Even though the Table is constructed by considering all four-dimensional Fano manifolds that occur as quiver flag zero loci in codimension up to four, in all four cases there is no tractable representative

³They are chosen to minimize the quantity $\sum_{i=0}^{\rho} r_i^2$, which is a rough proxy for the complexity of the Chow ring of the Abelianization.

as a quiver flag zero locus of low codimension. In these cases the Table contains a representative as a quiver flag zero locus in higher codimension; the reader who prefers models in lower-dimensional ambient spaces should consult Table 2.

Period ID	Adjacency matrix	Dimension vector	Generalized partitions
73	$\begin{matrix} 0 & 1 & 1 & 3 & 3 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \end{matrix}$	1 2 2 2 2	$(\emptyset, \square, \square, \emptyset)$
144	$\begin{matrix} 0 & 3 & 1 & 2 & 3 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \end{matrix}$	1 1 2 2 2	$(\emptyset, \square, \square, \emptyset)$
439	$\begin{matrix} 0 & 1 & 5 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{matrix}$	1 4 4	$\left(\begin{smallmatrix} \square \\ \square \end{smallmatrix}, \emptyset\right), \left(\begin{smallmatrix} \square \\ \square \end{smallmatrix}, \emptyset\right), \left(\begin{smallmatrix} \square \\ \square \end{smallmatrix}, \emptyset\right), \left(\begin{smallmatrix} \square \\ \square \end{smallmatrix}, \emptyset\right)$
552	$\begin{matrix} 0 & 0 & 5 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{matrix}$	1 2 4	$\left(\square, \begin{smallmatrix} \square \\ \square \end{smallmatrix}\right), \left(\begin{smallmatrix} \square \\ \square \end{smallmatrix}, \emptyset\right), \left(\begin{smallmatrix} \square \\ \square \end{smallmatrix}, \emptyset\right)$

TABLE 2. Representatives for certain Period IDs in codimension at most four

Remark B.1. *The data in Tables 1 and 2 can also be found, in machine readable form, in the ancillary files that accompany this paper.*

B.2. The table of period sequences. Table 2 records the first 8 terms of the period sequence, $\alpha_0, \alpha_1, \dots, \alpha_7$, for each of the 749 period sequence buckets. It also records, where they exist, the names of known four-dimensional Fano manifolds which have the same first fifteen terms of the period sequence. Notation is as follows:

- \mathbb{P}^n denotes n -dimensional complex projective space;
- Q^n denotes a quadric hypersurface in \mathbb{P}^{n+1} ;
- FI_k^4 is the k th four-dimensional Fano manifold of index 3, as in [5, §5];
- V_k^4 is the k th four-dimensional Fano manifold of index 2 and Picard rank 1, as in [5, §6.1];
- MW_k^4 is the k th four-dimensional Fano manifold of index 2 and Picard rank at least 2, as in [5, §6.2];
- BOS_k^4 is the k th four-dimensional toric Fano manifold, as in [5, §7];
- Str_k are the Strangeway fourfolds described in [5, §8];
- CKP_k is the k th four-dimensional toric complete intersection, as in [6];
- S_k^2 denotes the del Pezzo surface of degree k ;
- V_k^3 denotes the three-dimensional Fano manifold of Picard rank 1, Fano index 1, and degree k ;
- B_k^3 denotes the three-dimensional Fano manifold of Picard rank 1, Fano index 2, and degree $8k$;
- $\text{MM}_{\rho-k}^3$ denotes the k th entry in the Mori–Mukai list of three-dimensional Fano manifolds of Picard rank ρ [8–12]. We use the ordering as in [4], which agrees with the original papers of Mori–Mukai except when $\rho = 4$.

Remark B.2. *It appears from Table 2 as if the period sequences with IDs 72 and 73 might coincide. This is not the case. The coefficients α_8 , α_9 , and α_{10} in these cases are:*

Period ID	α_8	α_9	α_{10}
72	32830	212520	1190952
73	32830	227640	1190952

Remark B.3. 590 of the period sequences that we find coincide with period sequences for toric complete intersections, at least for the first 15 terms. 579 of these are realised by quiver flag zero loci that are also toric complete intersections. For the remaining 11 cases – period sequences with IDs 17, 48, 73, 144, 145, 158, 191, 204, 256, 280, and 282 – there is no model as a toric complete intersection that is also a quiver flag zero locus in codimension at most four. In four of these cases – with IDs 17, 48, 144, and 256 – the toric complete intersection period sequence is realised by a smooth four-dimensional toric variety.

Remark B.4. An earlier version of this paper omitted two of the period sequences that we find below, due to erroneous hand calculations in special cases. In this version all computations are performed in software, in a uniform way; we believe that this makes them more likely to be correct.

Funding statement.
