

# Supplementary Materials for

## **Population viability at extreme sex-ratio skews produced by temperature-dependent sex determination**

Graeme C. Hays\*, Antonios D. Mazaris, Gail Schofield, Jacques-Olivier Laloë

\*Corresponding author. E-mail: [g.hays@deakin.edu.au](mailto:g.hays@deakin.edu.au)

Figs. S1-S4

Tables S1

References

Figure S1. The relationship between the incubation temperature and the primary sex ratio in sea turtle nests. Loggerhead (open circles), olive ridley (diamonds), hawksbill (triangles) and green turtles (crosshairs) data. A logistic model was fitted using the method of least squares ( $r^2 = 0.72$ ,  $p < 0.001$ ):  $f(x) = \frac{1}{1+e^{-1.3(x-29.1)}}$ . A Kruskal-Wallis rank sum test showed no significant difference in the distribution of residuals between all species ( $X^2 = 7.19$ ,  $df = 3$ ,  $p = 0.07$ ) showing the generality of this model fit across species. Data are extracted from: Ackerman RA. 1997. The nest environment and the embryonic development of sea turtles. In: Lutz PL, Musick JA, (editors). Biology of Sea Turtles. Boca Raton. USA, CRC Press, pp. 83-106.

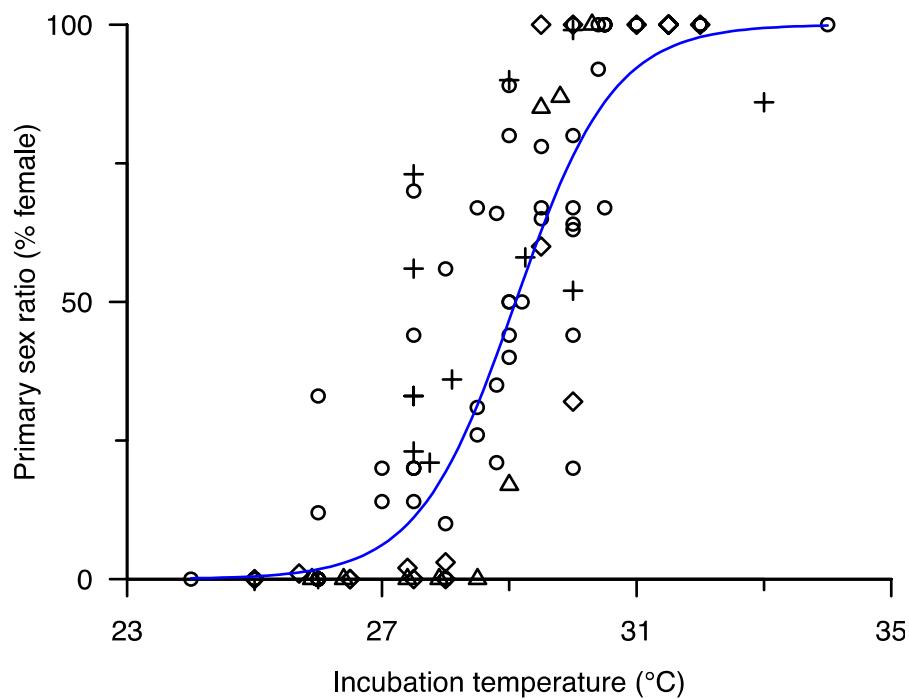

Figure S2. The relationship between the incubation temperature and hatching success in sea turtle nests. Loggerhead (open circles), olive ridley (diamonds), leatherback (triangles), flatback (crosses) and green turtles (crosshairs) data. A logistic model was fitted using the method of least squares ( $r^2 = 0.68$ ,  $p < 0.001$ ):  $f(x) = \frac{0.89}{1+e^{1.2(x-32.6)}}$ . A Kruskal-Wallis rank sum test on the residuals reveals that the function was a good fit for all species ( $X^2 = 4.35$ ,  $df = 4$ ,  $p = 0.36$ ). Data are extracted from: Howard R, Bell II, Pike DA. 2014. Thermal tolerances of sea turtle embryos: current understanding and future directions. Endangered Species Research 26: 75-86.

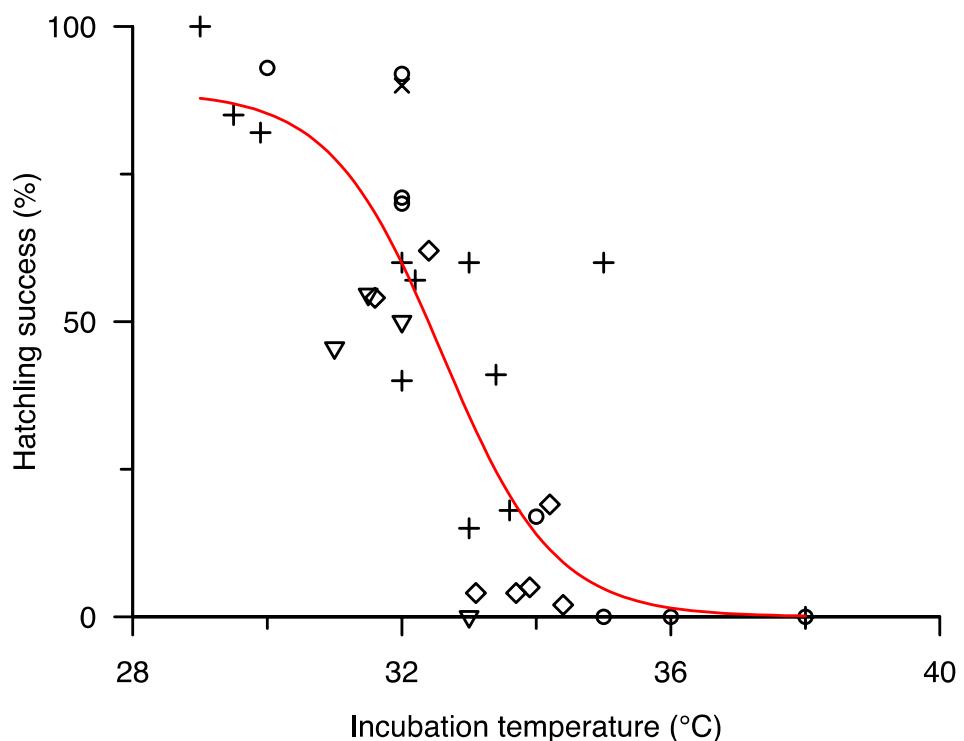

Figure S3. The effects of varying the pivotal temperature for TSD on the relationships between the incubation temperature and the primary sex ratio in nests and hatching success (first column), on the resulting numbers of male and female hatchlings surviving incubation (second column) and on the number of female hatchlings surviving expressed in relation to the primary sex ratio (third column). Points of inflection at 28.0, 29.1, and 30.0°C were modelled (first, second, and third row respectively).

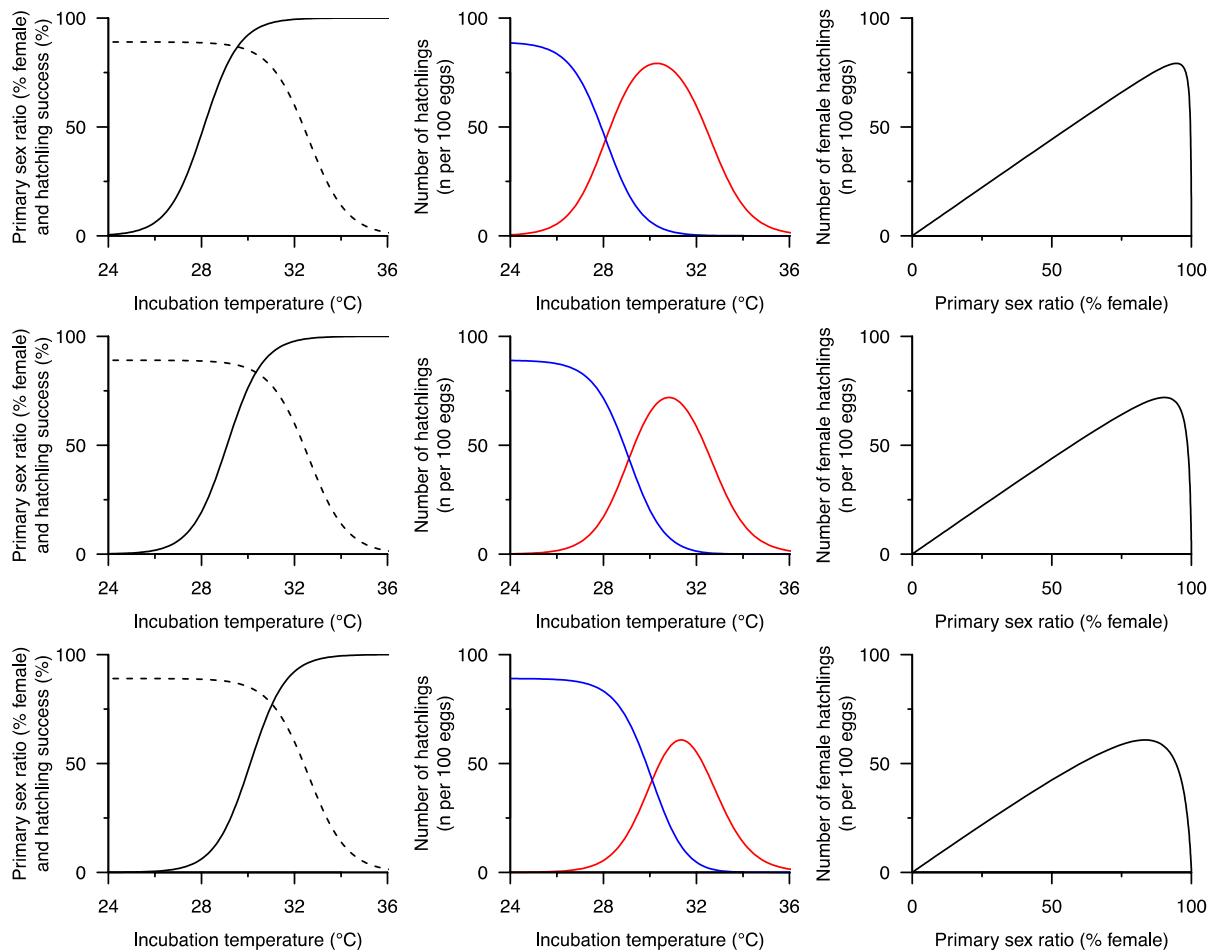

Figure S4. The effects of varying the point of inflection for hatchling survival on the relationships between the incubation temperature and the primary sex ratio in nests and hatching success (first column), on the resulting numbers of male and female hatchlings surviving incubation (second column) and on the number of female hatchling surviving expressed in relation to the primary sex ratio (third column). Points of inflection at 31.5, 32.6, and 33.5°C were modelled (first, second, and third row respectively).

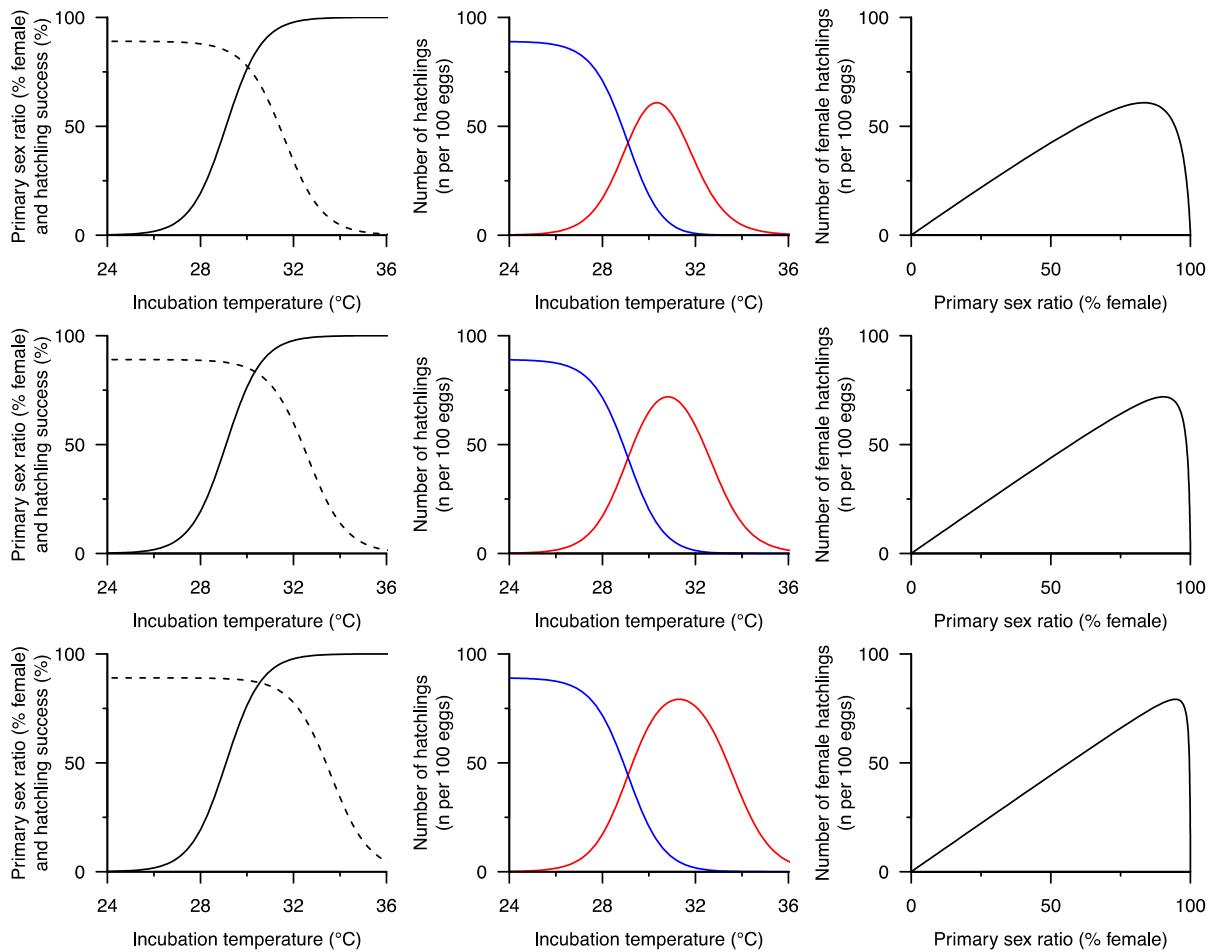

Table S1. **Sex ratio and population size data sources.** CM = *Chelonia mydas*; CC = *Caretta caretta*; DC = *Dermochelys coriacea*; EI = *Eretmochelys imbricata*; LO = *Lepidochelys olivacea*; LK = *Lepidochelys kempii*; ND = *Natator depressus*. Semi colon separates histological examination data from incubation temperature/duration data in the Year and Source columns.

Footnotes

<sup>1</sup>Two methods were used to derive sex ratio; the mean value was taken.

<sup>2</sup>An additional study by DeGregorio et al. (91) also supported a strongly female biased population, but was quantitative values were not provided.

<sup>3</sup>25-84% female bias was presented in a "mixed" category (both histological and mean incubation temperatures).
